

As discussed, I am working on automatic document circulation with the workflow below.

This will require support from your side as follows:

To deploy and operate this solution, support from the IT Department will be required in two key areas. First, access to the organization's authentication service is needed to ensure that only authorized Ahmadiyya personnel can access the application using their organizational accounts. Ideally, this would include integration with the organization's identity management platform to support user authentication, role-based access control, Single Sign-On (SSO), and, where applicable, Multi-Factor Authentication (MFA). Second, a server environment is required to host the application and its database. The database will store workflow-related information such as document identifiers, document locations, and audit logs, while the actual document files will be stored separately in an approved document repository such as OneDrive. As the database will contain only metadata and workflow information, its storage requirements are expected to be relatively small. The preferred architecture is for the application and database to be hosted on an on-premises server.

In summary, the application will be hosted on an on-premises server and accessed through a web-based interface by authorized users. The solution will integrate with the organization's authentication service for user login and access management, while documents will be stored in the organization's designated document repository, such as OneDrive.
